

Midterm results

- **Mean: 43, median: 40**

Midterm results

- Systems students should insist on a CDF!

Administrivia

- Lab 2 section this Friday, 12:30pm Skilling
- Pick up your midterm right now
- If you didn't pick up midterm in class, get it in Gates 279

Today's Big Adventure

- How to name and refer to things that don't exist yet
- How to merge separate name spaces into a cohesive whole
- More information:
 - [How to write shared libraries](#)
 - Run “nm,” “objdump,” and “readelf” on a few .o and a.out files.
 - [The ELF standard](#)
 - Examine [/usr/include/elf.h](#)

How is a program executed?

- On Unix systems, read by “loader”

- Reads all code/data segments into buffer cache;
Maps code (read only) and initialized data (r/w) into addr space
- Or...fakes process state to look like paged out
- Lots of optimizations happen in practice:**
 - Zero-initialized data does not need to be read in.
 - Demand load: wait until code used before get from disk
 - Copies of same program running? Share code
 - Multiple programs use same routines: share code

x86 Assembly syntax

- Linux uses **AT&T assembler syntax** – places destination last
 - Be aware that *intel syntax* (used in manual) places destination first
- **Types of operand available:**
 - Registers start with “%” – `movl %edx,%eax`
 - Immediate values (constants) prefixed by “\$” – `movl $0xff,%edx`
 - `(%reg)` is value at address in register `reg` – `movl (%edi),%eax`
 - `n(%reg)` is value at address in (register `reg`)+`n` – `movl 8(%ebp),%eax`
 - `*%reg` in an indirection through `reg` – `call %eax`
 - Everything else is an address – `movl var,%eax`; `call printf`
- **Some heavily used instructions**
 - `movl` – moves (copies) value from source to destination
 - `pushl/popl` – pushes/pops value on stack
 - `call` – pushes next instruction address to stack and jumps to target
 - `ret` – pops address of stack and jumps to it
 - `leave` – equivalent to `movl %ebp,%esp`; `popl %ebp`

Perspectives on memory contents

- **Programming language view:** `x += 1; add $1, %eax`
 - **Instructions:** Specify operations to perform
 - **Variables:** Operands that can change over time
 - **Constants:** Operands that never change
- **Hardware view:**
 - **executable:** code, usually read-only
 - **read only:** constants (maybe one copy for all processes)
 - **read/write:** variables (each process needs own copy)
- **Need *addresses* to use data:**
 - Addresses locate things. Must update them when you move
 - Examples: linkers, garbage collectors, URL
- **Binding time: When is a value determined/computed?**
 - Early to late: Compile time, Link time, Load time, Runtime

Running example: hello program

- **Hello program**
 - Write friendly greeting to terminal
 - Exit cleanly
- **Microtechnology and programming language in today's computers ideally suited to solve this problem**

[demo]

Running example: hello program

- **Hello program**
 - Write friendly greeting to terminal
 - Exit cleanly
- **Microtechnology and programming language in today's computers ideally suited to solve this problem**

- **Concept should be familiar if you took 106B:**

```
int main() {  
    cout << "Hello, world!" << endl;  
    return 0;  
}
```

- **Today's lecture: 80 minutes on hello world**

Hello world – CS140-style

```
#include <sys/syscall.h>
int my_errno;
const char greeting[] = "hello world\n";

int my_write(int fd, const void *buf, size_t len)
{
    int ret;
    asm volatile ("int $0x80" : "=a" (ret)
                  : "0" (SYS_write),
                    "b" (fd), "c" (buf), "d" (len)
                  : "memory");
    if (ret < 0) {
        my_errno = -ret;
        return -1;
    }
    return ret;
}

int main() { my_write (1, greeting, my_strlen(greeting)); }
```

Examining `hello1.s`

- Watching video? Grab [the source](#) and try it yourself
- `gcc -S hello1.c` produces assembly output in `hello1.s`
- Check the definitions of `my_errno`, `greeting`, `main`, `my_write`
- `.globl` **symbol** makes *symbol* global
- Sections of `hello1.s` are directed to various segments
 - `.text` says put following contents into text segment
 - `.data`, `.rodata` says to put into data or read-only data
 - `.bss` is zero-initialized data (specify size, not value)
 - `.comm` *symbol,size,align* declares *symbol* and allows multiple definitions (like C but not C++)
- See how function calls push arguments to stack, then pop

```
pushl    $greeting    # Argument to my_strlen is greeting
call     my_strlen     # Make the call (length now in %eax)
addl     $4, %esp      # Must pop greeting back off stack
```

Disassembling `hello1`

```
my_write (1, greeting, my_strlen(greeting));
80482d0: 68 c0 83 04 08      push    $0x80483c0
80482d5: e8 92 ff ff ff      call    804826c <my_strlen>
80482da: 83 c4 04            add     $0x4,%esp
80482dd: 50                  push    %eax
80482de: 68 c0 83 04 08      push    $0x80483c0
80482e3: 6a 01              push    $0x1
80482e5: e8 a9 ff ff ff      call    8048293 <my_write>
80482ea: 83 c4 0c            add     $0xc,%esp
```

- **Disassemble from shell with** `objdump -Sr hello1`
- **Offsets in `call` instructions:** `0xffffffff92 = -110`, `0xffffffffa9 = -87`
 - Binary encoding takes offset relative to next instruction
- **Note `push` encodes address of greeting (`0x80483c0`)**

How is a process specified?

```
$ readelf -h hello1
```

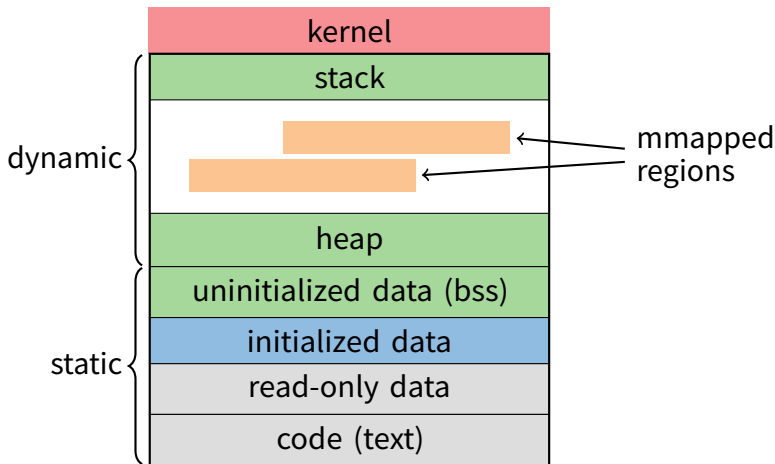

ELF Header:

...

Entry point address:	0x8048120
Start of program headers:	52 (bytes into file)
Number of program headers:	4
Start of section headers:	4364 (bytes into file)
Number of section headers:	24
Section header string table index:	21

- **Executable files are the linker/loader interface. Must tell OS:**
 - What is code? What is data? Where should they live?
 - This is part of the purpose of [the ELF standard](#)
- **Every ELF file starts with ELF an *header***
 - Specifies *entry point* virtual address at which to start executing
 - But how should the loader set up memory?

Recall what process memory looks like

- **Address space divided into “segments”**
 - Text, read-only data, data, bss, heap (dynamic data), and stack
 - Recall gcc told assembler in which segments to put what contents

Who builds what?

- **Heap: allocated and laid out at runtime by malloc**
 - Namespace constructed dynamically, managed by *programmer* (names stored in pointers, and organized using data structures)
 - Compiler, linker not involved other than saying where it can start
- **Stack: allocated at runtime (func,. calls), layout by compiler**
 - Names are relative off of stack (or frame) pointer
 - Managed by compiler (alloc on procedure entry, free on exit)
 - Linker not involved because name space entirely local: Compiler has enough information to build it.
- **Global data/code: allocated by compiler, layout by *linker***
 - Compiler emits them and names with symbolic references
 - Linker lays them out and translates references
- **Mmapped regions: Managed by programmer or linker**
 - Some programs directly call `mmap`; dynamic linker uses it, too

ELF program header

```
$ readelf -l hello1
```

Program Headers:

Type	Offset	VirtAddr	PhysAddr	FileSiz	MemSiz	Flg	Align
LOAD	0x000000	0x08048000	0x08048000	0x004d4	0x004d4	R E	0x1000
LOAD	0x0004d4	0x080494d4	0x080494d4	0x00024	0x00044	RW	0x1000
...							

Section to Segment mapping:

Segment Sections...

00	.text	.rodata	...
01	.data	.bss	...
...			

- **For executables, the ELF header points to a *program header***
 - Says what segments of file to map where, with what permissions
- **Segment 01 has shorter file size then memory size**
 - Only 0x24 bytes must be read into memory from file
 - Remaining 0x20 bytes constitute the .bss
- **Who creates the program header? The linker**

Linkers (Linkage editors)

- **Unix: ld**
 - Usually hidden behind compiler
 - Run `gcc -v hello.c` to see ld or invoked (may see collect2)
- **Three functions:**
 - Collect together all pieces of a program
 - Coalesce like segments
 - Fix addresses of code and data so the program can run
- **Result: runnable program stored in new object file**
- **Why can't compiler do this?**
- **Usually linkers don't rearrange segments, but can**
 - E.g., re-order instructions for fewer cache misses;
remove routines that are never called from `a.out`

Linkers (Linkage editors)

- **Unix: ld**
 - Usually hidden behind compiler
 - Run `gcc -v hello.c` to see ld or invoked (may see collect2)
- **Three functions:**
 - Collect together all pieces of a program
 - Coalesce like segments
 - Fix addresses of code and data so the program can run
- **Result: runnable program stored in new object file**
- **Why can't compiler do this?**
 - Limited world view: sees one file, rather than all files
- **Usually linkers don't rearrange segments, but can**
 - E.g., re-order instructions for fewer cache misses; remove routines that are never called from `a.out`

Simple linker: two passes needed

- **Pass 1:**
 - Coalesce like segments; arrange in non-overlapping memory
 - Read files' symbol tables, construct global symbol table with entry for every symbol used or defined
 - Compute virtual address of each segment (at start+offset)
- **Pass 2:**
 - Patch references using file and global symbol table
 - Emit result
- **Symbol table: information about program kept while linker running**
 - Segments: name, size, old location, new location
 - Symbols: name, input segment, offset within segment

Where to put emitted objects?

- **Assembler:**

- Doesn't know where data/code should be placed in the process's address space
- Assumes each segment starts at zero
- Emits **symbol table** that holds the name and offset of each created object
- Routines/variables exported by file are recorded as **global definitions**

- **Simpler perspective:**

- Code is in a big char array
- Data is in another big char array
- Assembler creates (object name, index) tuple for each interesting thing
- Linker then merges all of these arrays

0	main:
	:
	call my_write
	:
	ret
60	my_strlen:
	:
	ret
	main: 0: T
	my_strlen: 60: t
	greeting: 0: R

Object files

```
$ objdump -Sr hello2.o
...
48:    50                push    %eax
49:    68 00 00 00 00    push    $0x0
                        4a: R_386_32    greeting
4e:    6a 01                push    $0x1
50:    e8 fc ff ff ff    call    51 <main+0x2a>
                        51: R_386_PC32    my_write
55:    83 c4 10                add     $0x10,%esp
```

- **Let's create two-file program** `hello2` **with** `my_write` **in** **separate file**
 - Compiler and assembler can't possibly know final addresses
- **Notice** `push` **uses 0 as address of** `greeting`
- **And** `call` **uses -4 as address of** `my_write`—**why?**

Object files

```
$ objdump -Sr hello2.o
...
48:    50                push    %eax
49:    68 00 00 00 00    push    $0x0
                        4a: R_386_32    greeting
4e:    6a 01                push    $0x1
50:    e8 fc ff ff ff    call    51 <main+0x2a>
                        51: R_386_PC32    my_write
55:    83 c4 10                add     $0x10,%esp
```

- **Let's create two-file program** `hello2` **with** `my_write` **in separate file**
 - Compiler and assembler can't possibly know final addresses
- **Notice** `push` **uses 0 as address of** `greeting`
- **And** `call` **uses -4 as address of** `my_write`—**why?**
 - Target (sitting at offset 51 in text) encoded relative to next instruction (add at offset 55)

Where is everything?

- How to call procedures or reference variables?

- E.g., call to `my_write` needs a target addr
- Assembler uses 0 or PC (`%eip`) for address
- Emits an **external reference** telling the linker the instruction's offset and the symbol it needs to be patched with

0	main:
	⋮
49	pushl \$0x0
4e	pushl \$0x1
50	call -4
	⋮
main: 0: T	
my_strlen: 40: t	
greeting: 4a	
my_write: 51	

- At link time the linker patches every reference

Relocations

```
$ readelf -r hello2.o
```

```
  :  
Offset      Info      Type           Sym.Value    Sym. Name  
00000039    00000f01  R_386_32      00000000    greeting  
0000004a    00000f01  R_386_32      00000000    greeting  
00000051    00001102  R_386_PC32    00000000    my_write  
  :
```

- **Object file stores list of required relocations**
 - R_386_32 says add symbol value to value already in file (often 0)
 - R_386_PC32 says add difference between symbol value and patch location to value already in file (often -4 for call)
 - Info encodes type and index of symbol value to use for patch

ELF sections

```
$ readelf -S hello2.o
```

[Nr]	Name	Type	Addr	Off	Size	ES	Flg	Lk	Inf	Al
[0]		NULL	00000000	000000	000000	00		0	0	0
[1]	.text	PROGBITS	00000000	000034	0000a4	00	AX	0	0	1
[2]	.rel.text	REL	00000000	000744	000018	08	I 19		1	4
[3]	.data	PROGBITS	00000000	0000d8	000000	00	WA	0	0	1
[4]	.bss	NOBITS	00000000	0000d8	000000	00	WA	0	0	1
[5]	.rodata	PROGBITS	00000000	0000d8	00000d	00	A	0	0	4
:										
[19]	.symtab	SYMTAB	00000000	0005d4	000130	10		20	15	4

- Memory segments have corresponding PROGBITS file segments
- But relocations and symbol tables reside in segments, too
- Also segments can be arrays of fixed-size data structures
 - So strings referenced as offsets into special string segments
- Remember ELF header had section header string table index
 - That's so you can interpret names in section header

Symbol table

```
$ readelf -s hello2.o
```

Num:	Value	Size	Type	Bind	Vis	Ndx	Name
	:						
5:	00000000	39	FUNC	LOCAL	DEFAULT	1	my_strlen
	:						
15:	00000000	13	OBJECT	GLOBAL	DEFAULT	5	greeting
16:	00000027	62	FUNC	GLOBAL	DEFAULT	1	main
17:	00000000	0	NOTYPE	GLOBAL	DEFAULT	UND	my_write
	:						

- **Lists all global, exported symbols**
 - Sometimes local ones, too, for debugging (e.g., `my_strlen`)
- **Each symbol has an offset in a particular section number**
 - On previous slide, 1 = `.text`, 5 = `.rodata`
 - Special undefined section 0 means need symbol from other file

How to lay out emitted objects?

- **At link time, linker first:**
 - Coalesces all like segments (e.g., all `.text`, `.rodata`) from all files
 - Determines the size of each segment and the resulting address to place each object at
 - Stores all global definitions in a global symbol table that maps the definition to its final virtual address
- **Then in a second phase:**
 - Ensure each symbol has exactly 1 definition (except weak syms.)
 - For each relocation:
 - ▷ Look up referenced symbol's virtual address in symbol table
 - ▷ Fix reference to reflect address of referenced symbol

What is a library?

- A static library is just a collection of `.o` files
- Bind them together with `ar` program, much like `tar`
 - E.g., `ar cr libmylib.a obj1.o obj2.o obj3.o`
 - On many OSes, run `ranlib libmylib.a` (to build index)
- You can also list (`t`) and extract (`x`) files
 - E.g., try: `ar tv /usr/lib/libc.a`
- When linking a `.a` (archive) file, linker only pulls in needed files
 - Ensures resulting executable can be smaller than big library
- `readelf` will operate on every archive member (unweildy)
 - But often convenient to disassemble with `objdump -d /usr/lib/libc.a`

Examining programs with nm

```
int uninitialized;  
int initialized = 1;  
const int constant = 2;  
int main ()  
{  
    return 0;  
}
```

VA \$ nm a.out symbol type

...
0400400 T _start
04005bc R constant
0601008 W data_start
0601020 D initialized
04004b8 T main
0601028 B uninitialized

- If don't need full readelf, can use nm (nm -D on shared objects)
 - Handy -o flag prints file, handy with grep
- R means read-only data (.rodata in elf)
 - Note constant VA on same page as main
 - Share pages of read-only data just like text
- B means uninitialized data in "BSS"
- Lower-case letters correspond to local symbols

Examining sections with objdump

Note Load mem addr. and File off have same page alignment for easy mmaping

```
$ objdump -h a.out
```

```
a.out:      file format elf64-x86-64
```

```
Sections:
```

Idx	Name	Size	VMA	LMA	File off	Algn
12	.text	000001a8	00400400	00400400	00000400	2**4
	CONTENTS, ALLOC, LOAD, READONLY, CODE					
14	.rodata	00000008	004005b8	004005b8	000005b8	2**2
	CONTENTS, ALLOC, LOAD, READONLY, DATA					
17	.ctors	00000010	00600e18	00600e18	00000e18	2**3
	CONTENTS, ALLOC, LOAD, DATA					
23	.data	0000001c	00601008	00601008	00001008	2**3
	CONTENTS, ALLOC, LOAD, DATA					
24	.bss	0000000c	00601024	00601024	00001024	2**2
	ALLOC					
...						

No contents in file

- Another portable alternative to `readelf`

Name mangling

```
// C++
int foo (int a)
{
    return 0;
}

int foo (int a, int b)
{
    return 0;
}
```

```
% nm overload.o
00000000 T _Z3fooi
0000000e T _Z3fooui
               U __gxx_personality_v0
```

Mangling not compatible across compiler versions

Demangle names

```
% nm overload.o | c++filt
00000000 T foo(int)
0000000e T foo(int, int)
               U __gxx_personality_v0
```

- C++ can have many functions with the same name
- Compiler therefore *mangles* symbols
 - Makes a unique name for each function
 - Also used for methods/namespaces (obj::fn), template instantiations, & special functions such as operator new

Initialization and destruction

```
// C++
int a_foo_exists;
struct foo_t {
    foo_t () {
        a_foo_exists = 1;
    }
};
foo_t foo;
```

- **Initializers run before main**

- Mechanism is platform-specific

- **Example implementation:**

- Compiler emits static function in each file running initializers
- Wrap linker with `collect2` program that generates `__main` function calling all such functions
- Compiler inserts call to `__main` when compiling real `main`

```
% cc -S -o- ctor.C | c++filt
```

```
...
        .text
        .align 2
__static_initialization_and_destruction_0(int, int):
...
        call    foo_t::foo_t()
```

Other information in executables

```
// C++
struct foo_t {
    ~foo_t() { /*...*/ }
    except() { throw 0; }
};

void fn ()
{
    foo_t foo;
    foo.except();
    /* ... */
}
```

- **Throwing exceptions destroys automatic variables**
 - **During exception, must find**
 - All such variables with non-trivial destructors
 - In all procedures' call frames until exception caught
 - **Record info in special sections**
- **Executables can include debug info (compile w. -g)**
 - What source line does each binary instruction correspond to?

Dynamic (runtime) linking (hello3.c)

```
#include <dlfcn.h>
int main(int argc, char **argv, char **envp)
{
    size_t (*my_strlen)(const char *p);
    int (*my_write)(int, const void *, size_t);
    void *handle = dlopen("dest/libmy.so", RTLD_LAZY);
    if (!handle
        || !(my_strlen = dlsym(handle, "my_strlen"))
        || !(my_write = dlsym(handle, "my_write")))
        return 1;
    return my_write(1, greeting, my_strlen(greeting)) < 0;
}
```

- **Link time isn't special, can link at runtime too**
 - Get code (e.g., plugins) not available when program compiled
- **Issues:**
 - How can behavior differ compared to static linking?
 - Where to get unresolved symbols (e.g., `my_write`) from?
 - How does `my_write` know its own addresses (e.g., for `my_errno`)?

Dynamic linking (continued)

- **How can behavior differ compared to static linking?**
 - Runtime failure (can't find file, doesn't contain symbols)
 - No type checking of functions, variables
- **Where to get unresolved symbols (e.g., `my_write`) from?**
 - `dlsym` must parse ELF file to find symbols
- **How does `my_write` know its own addresses?**

```
$ readelf -r dest/libmy.so
```

```
Relocation section '.rel.dyn' at offset 0x204 contains 1 entries:
```

Offset	Info	Type	Sym.Value	Sym. Name
000013bc	00000306	R_386_GLOB_DAT	000013cc	my_errno

- `dlopen`, too, must parse ELF to patch relocations

Static shared libraries

- Observation: everyone links in standard libraries (libc.a.), these libs consume space in every executable.

- Insight: we can have a single copy on disk if we don't actually include libc code in executable

Static shared libraries

- Define a “shared library segment” at same address in every program’s address space

- Every shared lib is allocated a unique range in this seg, and computes where its external defs reside
- Linker links program against lib (why?) but does not bring in actual code

- Loader marks shared lib region as unreadable
- When process calls lib code, seg faults: embedded linker brings in lib code from known place & maps it in.
- Now different running programs can share code!

Dynamic shared libraries

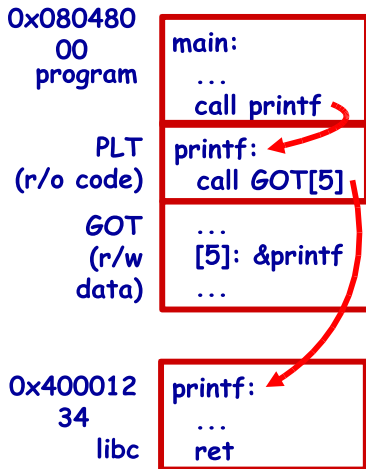

- **Static shared libraries require system-wide pre-allocation of address space**
 - Clumsy, inconvenient
 - What if a library gets too big for its space? (fragmentation)
 - Can space ever be reused?
- **Solution: Dynamic shared libraries**
 - Combine shared library and dynamic linking ideas
 - Any library can loaded at any VA, chosen at runtime
- **New problem: Linker won't know what names are valid**
 - Solution: stub library
- **New problem: How to call functions whose position varies?**
 - Solution: next page...

Position-independent code

- Code must be able to run anywhere in virtual mem
- Runtime linking would prevent code sharing, so...
- Add a level of indirection!

Static Libraries

Dynamic Shared Libraries

Lazy dynamic linking

0x08048000
program

main:

...
call printf

PLT
(r/o code)

printf:
call GOT[5]

GOT
(r/w data)

...
[5]: dlfixup
...

- Linking all the functions at startup costs time
- Program might only call a few of them
- Only link each function on its first call

0x40001234
libc

printf:
...
ret

dlfixup:
GOT[5] = &printf
call printf

Dynamic linking with ELF

- **Every dynamically linked executable needs an *interpreter***
 - Embedded as string in special `.interp` section
 - `readelf -p .interp /bin/ls → /lib64/ld-linux-x86-64.so.2`
 - So all the kernel has to do is run `ld-linux`
- `dlfixup` **uses hash table to find symbols when needed**
- **Hash table lookups can be quite expensive [Drepper]**
 - E.g., big programs like OpenOffice very slow to start
 - Solution 1: Use a better hash function
 - ▷ linux added `.gnu.hash` section, later removed `.hash` sections
 - Solution 2: Export fewer symbols. Now fashionable to use:
 - ▷ `gcc -fvisibility=hidden` (keep symbols local to DSO)
 - ▷ `#pragma GCC visibility push(hidden)/visibility pop`
 - ▷ `__attribute__((visibility("default")))`, (override for a symbol)

Dynamic shared library example: hello4

```
$ objdump -Sr hello4
```

```
      :  
08048300 <my_write@plt>:  
      8048300:      ff 25 58 97 04 08      jmp     *0x8049758  
      8048306:      68 00 00 00 00      push   $0x0  
      804830b:      e9 e0 ff ff ff      jmp     80482f0 <_init+0x2c>  
      :  
08048320 <my_strlen@plt>:  
      8048320:      ff 25 60 97 04 08      jmp     *0x8049760  
      8048326:      68 10 00 00 00      push   $0x10  
      804832b:      e9 c0 ff ff ff      jmp     80482f0 <_init+0x2c>  
      :  
      804843f:      68 30 85 04 08      push   $0x8048530  
      8048444:      e8 d7 fe ff ff      call   8048320 <my_strlen@plt>
```

- 0x8049758 **and** 0x8049760 **initially point to next instruction**
 - Calls `dlfixup` with relocation index
 - `dlfixup` needs no relocation because `jmp` takes relative address

hello4 relocations

```
$ readelf -r hello4
```

Relocation section '.rel.plt' at offset 0x2ac contains 3 entries:

Offset	Info	Type	Sym.Value	Sym. Name
08049758	00000107	R_386_JUMP_SLOT	00000000	my_write
0804975c	00000207	R_386_JUMP_SLOT	00000000	__gmon_start__
08049760	00000307	R_386_JUMP_SLOT	00000000	my_strlen

- **PLT = *procedure linkage table* on last slide**
 - Small 16 byte snippets, read-only executable code
- **dlfixup **Knows how to parse relocations, symbol table****
 - Looks for symbols by name in hash tables of shared libraries
- **my_write & my_strlen are pointers in *global offset table* (GOT)**
 - GOT non-executable, read-write (so dlfixup can fix up)
- **Note hello4 knows address of greeting, PLT, and GOT**
 - How does a shared object (libmy.so) find these?
 - PLT is okay because calls are relative
 - In PIC, compiler reserves one register %ebx for GOT address

hello4 shared object contents

mywrite.c

```
int my_errno;
int my_write(int fd, const void *buf, size_t len) {
    int ret;
    asm volatile (/* ... */);
    if (ret < 0) {
        my_errno = -ret;
        return -1;
    }
    return ret;
}
```

mywrite.s

```
negl %eax
movl %eax, my_errno
```

mywrite-pic.s

```
negl %eax
movl %eax, %edx
movl my_errno@GOT(%ebx), %eax
movl %edx, (%eax)
```

How does %ebx get set?

mywrite-pic.s

```
my_write:
    pushl    %ebp
    movl     %esp, %ebp
    pushl    %ebx
    subl     $16, %esp
    call     __x86.get_pc_thunk.bx
    addl     $_GLOBAL_OFFSET_TABLE_, %ebx
    :
__x86.get_pc_thunk.bx:
    movl     (%esp), %ebx
    ret
```

Linking and security

```
void fn ()  
{  
    char buf[80];  
    gets (buf);  
    /* ... */  
}
```

1. Attacker puts code in buf

- Overwrites return address to jump to code

2. Attacker puts shell command above buf

- Overwrites return address so function “returns” to `system` function in `libc`

- People try to address problem with linker
- W^X: No memory both writable and executable
 - Prevents 1 but not 2, must be disabled for jits
- Address space randomization
 - Makes attack #2 a little harder, not impossible
- Also address with compiler (stack protector, CFI)

Linking Summary

- **Compiler/Assembler: 1 object file for each source file**
 - Problem: incomplete world view
 - Where to put variables and code? How to refer to them?
 - Names definitions symbolically (`printf`), refers to routines/variable by symbolic name
- **Linker: combines all object files into 1 executable file**
 - Big lever: global view of everything. Decides where everything lives, finds all references and updates them
 - Important interface with OS: what is code, what is data, where is start point?
- **OS loader reads object files into memory:**
 - Allows optimizations across trust boundaries (share code)
 - Provides interface for process to allocate memory (`sbrk`)

Code = data, data = code

- **No inherent difference between code and data**

- Code is just something that can be run through a CPU without causing an “illegal instruction fault”
- Can be written/read at runtime just like data “dynamically generated code”

- **Why? Speed (usually)**

- Big use: eliminate interpretation overhead. Gives 10-100x performance improvement
- Example: Just-in-time compilers for java, or qemu vs. bochs.
- In general: optimizations thrive on information. More information at runtime.

- **The big tradeoff:**

- Total runtime = code gen cost + cost of running code

How?

- Determine binary encoding of desired instructions

SPARC: sub instruction

symbolic = "sub rdst, rsrc1, rsrc2"

- Write these integer values into a memory buffer

```
unsigned code[1024], *cp = &code[0];
```

```
/* sub %g5, %g4, %g3 */
```

```
*cp++ = (2<<30) | (5<<25) | (4<<19) |(4<<14) | 3;
```

```
...
```

- Jump to the address of the buffer:

```
((int (*)( ))code)();
```
